DISTRACTED WALKING STUDY: Topline Summary Findings

Research Conducted by Ipsos Public Affairs on behalf of
The American Academy of Orthopaedic Surgeons

These are findings from an Ipsos poll conducted October 8-20, 2015 on behalf the American Academy of Orthopaedic Surgeons. For the survey, a sample of 2,008 adults age 18+ from the continental U.S., Alaska and Hawaii was interviewed online in English.

The sample for this study was randomly drawn from Ipsos’ online panel (see link below for more info on “Access Panels and Recruitment”), partner online panel sources, and “river” sampling (see link below for more info on the Ipsos “Ampario Overview” sample method) and does not rely on a population frame in the traditional sense. Ipsos uses fixed sample targets, unique to each study, in drawing sample. After a sample has been obtained from the Ipsos panel, Ipsos calibrates respondent characteristics to be representative of the U.S. Population using standard procedures such as raking-ratio adjustments. The source of these population targets is U.S. Census 2015 American Community Survey data. The sample drawn for this study reflects fixed sample targets on demographics. Post-hoc weights were made to the population characteristics on gender, age, region, race/ethnicity and income.

Statistical margins of error are not applicable to online polls. All sample surveys and polls may be subject to other sources of error, including, but not limited to coverage error and measurement error. Where figures do not sum to 100, this is due to the effects of rounding. The precision of Ipsos online polls is measured using a credibility interval. In this case, the poll has a credibility interval of plus or minus 2.5 percentage points for all respondents (see link below for more info on Ipsos online polling “Credibility Intervals”). Ipsos calculates a design effect (DEFF) for each study based on the variation of the weights, following the formula of Kish (1965). This study had a credibility interval adjusted for design effect of the following (n=2,008, DEFF=1.5, adjusted Confidence Interval=4.0).

1. When you are doing each of the following activities, how focused are you on that activity?

Please select one response for each item

<table>
<thead>
<tr>
<th>Activity</th>

</table>

10. Distracted walking incidents can range from bumping into someone or something, to tripping/falling, or being hit by a moving vehicle while walking. These incidents happen as a result of being distracted by something you were doing while walking or as a result of someone else causing an incident because they were distracted while walking.

<table>
<thead>
<tr>
<th>Question</th>
<th>Yes</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Have you ever been in a distracted walking incident yourself?</td>
<td>26%</td>
<td>74%</td>
</tr>
<tr>
<td>Has someone in your family been involved in a distracted walking incident?</td>
<td>20%</td>
<td>80%</td>
</tr>
<tr>
<td>Do you know someone outside of your family who has been in a distracted walking incident?</td>
<td>27%</td>
<td>73%</td>
</tr>
<tr>
<td>Have you witnessed a distracted walking incident that you were not part of?</td>
<td>38%</td>
<td>62%</td>
</tr>
</tbody>
</table>

11. Thinking about your own distracted walking incident, what injuries resulted from that incident? If you’ve had more than one distracted walking incident, please think about the most recent distracted walking incident when responding.

Please select all that apply

*Asked of those that have been in a distracted walking accident at Q10, n=523*

<table>
<thead>
<tr>
<th>Injury Description</th>
<th>Yes Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>I just tripped or bumped into something, without injury</td>
<td>68%</td>
</tr>
<tr>
<td>I fell down to the ground, without injury</td>
<td>18%</td>
</tr>
<tr>
<td>I had scrapes and/or minor cuts</td>
<td>14%</td>
</tr>
<tr>
<td>I had significant cuts</td>
<td>3%</td>
</tr>
<tr>
<td>I had a painful, but minor injury, like a stubbed toe or twisted ankle</td>
<td>9%</td>
</tr>
<tr>
<td>I broke one or more bones</td>
<td>3%</td>
</tr>
</tbody>
</table>
12. Thinking about the actions from the previous questions that may result in distracted walking (texting, talking on a smartphone, etc.)...

Please select one response for each item

<table>

How to Calculate Bayesian Credibility Intervals

The calculation of credibility intervals assumes that $Y$ has a binomial distribution conditioned on the parameter $\theta$, i.e., $Y|\theta \sim \text{Bin}(n, \theta)$, where $n$ is the size of our sample. In this setting, $Y$ counts the number of “yes”, or “1”, observed in the sample, so that the sample mean ($\bar{y}$) is a natural estimate of the true population proportion $\theta$. This model is often called the likelihood function, and it is a standard concept in both the Bayesian and the Classical framework. The Bayesian statistics combines both the prior distribution and the likelihood function to create a posterior distribution. The posterior distribution represents our opinion about which are the plausible values for $\theta$ adjusted after observing the sample data. In reality, the posterior distribution is one’s knowledge base updated using the latest survey information. For the prior and likelihood functions specified here, the posterior distribution is also a beta distribution ($\pi(\theta/y) \sim \beta(y+a, n-y+b)$), but with updated hyper-parameters.

Our credibility interval for $\theta$ is based on this posterior distribution. As mentioned above, these intervals represent our belief about which are the most plausible values for $\theta$ given our updated knowledge base. There are different ways to calculate these intervals based on $\pi(\theta/y)$. Since we want only one measure of precision for all variables in the survey, analogous to what is done within the Classical framework, we will compute the largest possible credibility interval for any observed sample. The worst case occurs when we assume that $a=1$ and $b=1$ and $y=n/2$. Using a simple approximation of the posterior by the normal distribution, the 95% credibility interval is given by, approximately:

$$\bar{y} \pm \frac{1}{\sqrt{n}}$$

For this poll, the Bayesian Credibility Interval was adjusted using standard weighting design effect $1+L=1.3$ to account for complex weighting.

Examples of credibility intervals for different base sizes are below. Ipsos does not publish data for base sizes (sample sizes) below 100.
